

VOLTAGE REGULATORS PLUS FILTER

PRELIMINARY DATA

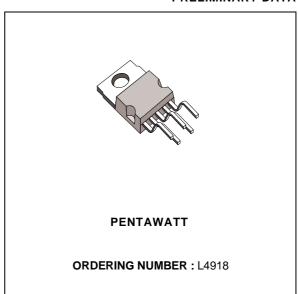

- FIXED OUTPUT VOLTAGE 8.5V
- 250mA OUTPUT CURRENT
- HIGH RIPPLE REJECTION
- HIGH LOAD REGULATION
- HIGH LINE REGULATION
- SHORT CIRCUIT PROTECTION
- THERMAL SHUT DOWN WITH HYSTERESIS
- DUMP PROTECTION

DESCRIPTION

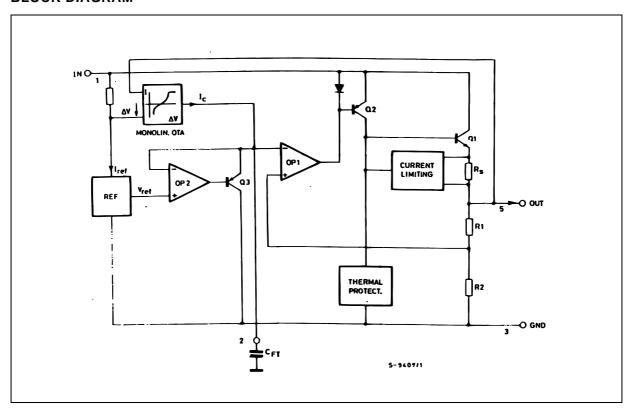

The L4918 combines both a filter and a voltage regulator in order to provide a high ripple rejection over a wider input voltage range.

A supervisor low-pass loop of the element prevents the output transistor from saturation at low input vol tages.

The non linear behaviour of this control circuitry allows a fast setting of the filter.

PRINCIPLE OF OPERATION

During normal operation (input voltage upper than $V_{I MIN} = V_{OUT NOM} + \Delta V_{I/O}$). The device works as a normal voltage regulator built around the OP1 of the block diagram.

The series pass element use a PNP-NPN connection to reduce the dropout. The reference voltage of the OP1 is derived from a REF through the OP2 and Q3, acting as an active zener diode of value V_{REF} . In this condition the device works in the range (1) of the characteristic of the non linear drop control unit (see fig.2).

The output voltage is fixed to its nominal value:

$$V_{OUT NOM} = V_{REF} (1 + \frac{R1}{R2}) = V_{CFT} (1 + \frac{R1}{R2})$$

 $\frac{R1}{R2} = INTERNALLY FIXED RATIO = 2.4$

The ripple rejection is quite high (71 dB) and independent from C_{FT} value.

On the usual voltage regulators, when the input voltage goes below the nominal value, the regulation transistors (series element) saturate bringing the system out of regulation making it very sensible to every variation of the input voltage. Onthe contrary, a control loop on the L4918 consents to avoid the saturation of the series element by regulating the value of the reference voltage (pin 2). In fact, whenever the input voltage decreases below V_{IMIN} the supervisor loop, utilizing a non linear OTA, forces the reference voltage at pin 2 to decrease by discharging C_{FT}. So, during the static mode, when the input voltage goes below V_{MIN} the drop out is kept fixed to about 1.6 V. In this condition the device works as a low pass filter in the range (2) of the OTA charac-

teristic. The ripple rejection is externally adjustable acting on C_{FT} as follows:

SVR (jw) =
$$\left| \frac{V_1 (jw)}{V_{out} (jw)} \right| = 1 + \left| \frac{10^{-6}}{\frac{gm}{jwC_{FT}} (1 + \frac{R1}{R_2})} \right|$$

Where:

gm = 2 . $10^{-5} \Omega^{-1}$ = OTA'S typical transconductance value on linear region

$$\frac{R1}{R2}$$
 = fixed ratio

Figure 2 : Nonliner Transfer Characteristic of the Drop Control Unit.

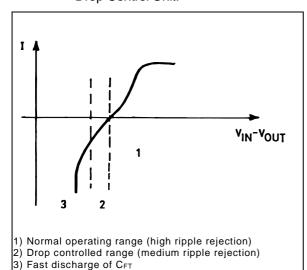

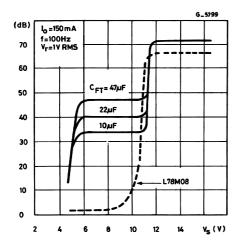

Figure 4: Supply voltage Rejection vs. Input Voltage.

 C_{FT} = value of capacitor in μF

The reaction time of the supervisor loop is given by the transconductance of the OTA and by C_{FT}. When the value of the ripple voltage is so high and its negative peak is fast/enough to determine an istantaneous decrease of the dropout till 1.2V, the OTA works in a higher transconductance condition [range (3) of the characteristic] and discharge the capacitor rapidously.

If the ripple frequency is high enough the capacitor won't charge itself completely, and the output voltage reaches a small value allowing a better ripple rejection; the device's again working as a filter (fast transient range).

With $C_{FT} = 10 \,\mu\text{F}$; $f = 100 \,\text{Hz}$ a SVR of 35 is obtained.
